High Precision Bearings for Combined Loads

Axial/radial bearings
Axial angular contact ball bearings
Axial/radial bearings with angular measuring system
Foreword

Focus on complete system

With trend-setting bearing arrangement solutions for feed spindles, main spindles, rotary tables and linear guidance units, Schaeffler has been at the forefront of the world market for decades. However, bearing components alone are often no longer the decisive factor for the success of these machine subsystems.

Indeed, our customers are continuing to benefit directly from significant performance improvements and unique selling points thanks to our “ready-to-fit” products, since these follow the efficient basic concept: unpack, screw mount, use. In order to optimise the entire machine tool system, however, it is also becoming ever more important to integrate important functions such as measurement, sealing, lubrication, braking etc. in the components themselves. This intellectual approach focusses consistently on the complete system, including the bearing and bearing position. This means that you can access a product range that gives optimum coverage for all your applications in the machine tool.

Direct drives and mechatronic solutions

In addition, there is increasingly frequent usage of direct drives and mechatronic solutions in machine tools. We therefore have IDAM – INA-Drives & Mechatronics – as a further strong partner in our provider network. In this way, we can supply you from a single source with not only bearing elements but also components precisely matched to the drive system.

This opens up completely new technical and economic design possibilities for your requirements as well as significant advantages in the time and process chain.

In terms of products, we can offer you a comprehensive, precisely balanced range, precision technology and top product quality. In order to match the pulse of your developments as closely as possible, we also have a worldwide network of engineers and service and sales technicians working for you and ensuring that we maintain close contact with you in your own location.

We are therefore confident that we have the right product for you, from a robust individual component right through to the defining high end system solution.
High precision bearings for combined loads

Axial/radial bearings

Axial/radial bearings are double direction axial bearings for screw mounting, with a radial guidance bearing. These ready-to-fit, greased units are very rigid, have high load carrying capacity and run with particularly high accuracy. They can support radial forces, axial forces from both directions and tilting moments free from clearance. The bearings are available in several series.

For applications with low speeds and small operating durations, such as indexing tables and swivel type milling heads, the most suitable bearings are generally series YRT and YRTC.

For the bearing arrangements of direct drive axes, there is the series YRTS. Due to their high limiting speeds and very low, uniform frictional torque across the whole speed range, these bearings are particularly suitable for combination with torque motors.

For higher accuracy requirements, these bearings are also available with restricted axial and radial runout accuracy.

Axial angular contact ball bearings

Axial angular contact ball bearings ZKLDF are low-friction, ready-to-fit, pregreased bearing units with high accuracy for very high speeds, high axial and radial loads and high demands on tilting rigidity.

Axial angular contact ball bearings are particularly suitable for precision applications involving combined loads. Their preferred areas of use are bearing arrangements in rotary tables with a main spindle function, for example in combined milling and turning, as well as in milling, grinding and honing heads and in measurement and testing equipment.

Axial/radial bearings with angular measuring system

Axial/radial bearings with angular measuring system YRTM and YRTSM correspond in mechanical terms to series YRT and YRTS, but are additionally fitted with an angular measuring system. The measuring system can measure angles to an accuracy of a few angular seconds by non-contact, magneto-resistive means.

Further information on axial/radial bearings with absolute value angular measuring systems YRTMA and YRTSMA can be found in special publication SSD 30, see page 78.

For higher speeds
YRTS

Axial angular contact ball bearings
ZKLDF
Axial/radial bearings
Axial angular contact ball bearings

Features
Axial radial bearings YRT, YRTC and YRTS and axial angular contact ball bearings ZKLDF are ready-to-fit high precision bearings for high precision applications with combined loads. They can support radial loads, axial loads from both sides and tilting moments without clearance and are particularly suitable for bearing arrangements with high requirements for running accuracy.

Due to the fixing holes in the bearing rings, the units are very easy to fit.

The bearings are radially and axially preloaded after fitting.

The mounting dimensions of all series are identical.

Axial/radial bearings YRT in the size range of \( d = 580 \) mm to \( d = 1,030 \) mm have been replaced by YRTC.

Compared with the predecessor product YRT, these bearings have higher rigidity, a higher limiting speed and lower bearing friction.

With angular measuring system
Axial/radial bearings are also available with an absolute value angular measuring system or have systems with pitch-coded reference marks. The measuring systems can measure angles to an accuracy of a few angular seconds by non-contact means, see page 44 and page 78.

Areas of application
For standard applications with low speeds and small operating durations, such as indexing tables and swivel type milling heads, the most suitable bearings are generally series YRT and YRTC, Figure 1.

For the bearing arrangements of direct drive axes, there is the series YRTS. Due to their high limiting speeds and very low, uniform frictional torque across the whole speed range, these bearings are particularly suitable for combination with torque motors, Figure 1.

For higher accuracy requirements, these bearings are also available with restricted axial and radial runout accuracy.

Axial angular contact ball bearings ZKLDF are particularly suitable for high speed applications with long operating duration, Figure 1. They are characterised by high tilting rigidity, low friction and low lubricant consumption.

\[ n_0 = \text{limiting speed} \]
\[ c_{\mu} = \text{tilting rigidity} \]

Figure 1
Speed and tilting rigidity
Axial/radial bearings
Axial angular contact ball bearings

Axial/radial bearings
Axial/radial bearings YRT, YRTC and YRTS have an axial and a radial component.
The axial component comprises an axial needle roller or cylindrical roller and cage assembly, an outer ring, L-section ring and shaft locating washer and is axially preloaded after fitting. The radial component is a full complement cylindrical roller set in YRT and a cage-guided, preloaded cylindrical roller set in YRTC and YRTS. The outer ring, L-section ring and shaft locating washer have fixing holes.
The unit is located by means of retaining screws for transport and safe handling.

Sealing
Axial/radial bearings are supplied without seals.

Lubrication
The initial greasing of YRTS corresponds to the grease Arcanol LOAD150 and, in the case of YRT and YRTC, to the grease Arcanol MULTITOP. The bearings can be lubricated via the outer ring and L-section ring.

Axial angular contact ball bearings
Axial angular contact ball bearings ZKLDF comprise a single-piece outer ring, a two-piece inner ring and two ball and cage assemblies with a contact angle of 60°. The outer ring and inner ring have fixing holes for screw mounting of the bearing on the adjacent construction.
The unit is located by means of retaining screws for transport and safe handling.

Sealing
Axial angular contact ball bearings have sealing shields on both sides.

Lubrication
The initial greasing of current axial angular contact ball bearings ZKLDF (Generation B) corresponds to the grease Arcanol MULTITOP. The bearings can be relubricated via the outer ring.

Operating temperature
Axial/radial bearings and axial angular contact ball bearings are suitable for operating temperatures from –30 °C to +120 °C.

Design and safety guidelines

General safety guidelines
The general safety guidelines must be observed. Further information relating to safety of control circuits: see Axial/radial bearings with angular measuring system, page 44.

Protection against accidental contact (DIN EN 60529)
The guidelines on protection against accidental contact in accordance with DIN EN 60529 must be observed.

After fitting, rotating components must be provided with adequate protection against accidental contact in operation.

Usage for the intended purpose
The products in this publication are suitable for use in chip-forming machine tools and in particular for the bearing arrangements of high precision rotary axes in milling and turning machines. Any usage outside the specified area or for purposes other than that intended is at the personal responsibility of the user.

Further information relating to bearings with angular measuring system: see page 67.

Modifications to the product
Modifications to the product are not permissible and will invalidate the warranty.

Machine safety under the terms of the Machinery Directive
The following rotary table bearings are, under the terms of the Machinery Directive 2006/42/EC, a component for integration in a complete system (finished or unfinished machine). The data and tests given in this publication relate purely to the components and are not a substitute for the detailed tests of the complete system.

Operating time
The mean operating time between two failures is described as the MTBF (Mean Time Between Failure). This can be calculated by agreement for rolling bearings and angular measuring devices. The operating time for rolling bearings is calculated on the basis of the load and speed duty cycle.
Axial/radial bearings
Axial angular contact ball bearings

Basic rating life
The load carrying capacity and life must be checked for the radial and axial bearing component.
Please contact us in relation to checking of the basic rating life.
The speed, load and operating duration must be given.

Static load safety factor
The static load safety factor $S_0$ indicates the security against impermissible permanent deformations in the bearing:

$$S_0 = \frac{C_{0r} \text{ or } C_{0a}}{F_{0r} \text{ or } F_{0a}}$$

- $S_0$: Static load safety factor
- $C_{0r}$, $C_{0a}$: Basic static load rating according to dimension tables
- $F_{0r}$, $F_{0a}$: Maximum static load on the radial or axial bearing.

In machine tools and similar areas of application, $S_0$ should be $> 4$.

Static limiting load diagrams
The static limiting load diagrams can be used:
- for rapid checking of the selected bearing size under predominantly static load
- for calculation of the tilting moment $M_k$ that can be supported by the bearing in addition to the axial load.

The limiting load diagrams are based on a rolling element set with a static load safety factor $S_0 \geq 4$, as well as the screw and bearing ring strength.

The static limiting load must not be exceeded when dimensioning the bearing, Figure 2 to Figure 9, page 13.

$M_k$ = maximum tilting moment
$F_a$ = axial load

Limiting speeds
In bearing selection, the following guidelines and the limiting speeds must be observed, see dimension tables.

If the environmental conditions differ from the specifications in relation to adjacent construction tolerances, lubrication, ambient temperature, heat dissipation or from the normal operating conditions for machine tools, the stated limiting speeds must be checked. Please contact us.

Axial/radial bearing YRT
Axial/radial bearings YRT are designed, by means of the full complement radial roller bearing component for high rigidity, for rapid positioning and operating at low speed. Low speeds are normally required for multiple-axis simultaneous machining. The limit value $n_G$ stated in the dimension tables relates to the maximum swivel speed and a maximum speed applied for a short period.

In applications with a high operating duration $ED$ or continuous operation at a speed of more than $n \times d = 35 \times 10^3 \text{ min}^{-1} \cdot \text{mm}$ at an $ED > 10\%$, the series YRTS or ZKLDF should be selected.

Axial radial bearings YRTC, YRTS and axial angular contact ball bearings ZKLDF
The limiting speeds $n_C$ stated for these bearing series were determined on test rigs.

During the test, the following conditions apply:
- grease distribution cycle according to the defined data, see Figure 15, page 21
- maximum increase in bearing temperature of $40 \text{ K}$ in the area of the raceway
- operating duration $ED = 100\%$, which means continuous operation at the limiting speed $n_G$
- bearing fully screw mounted on solid fixtures
- no external load, only preload and mass of the fixtures.
Temperature distribution in the rotary axis system

Rotary axes with a main spindle function, such as those used for combined milling and turning and with direct drive by a torque motor, are systems with complex thermal characteristics.

The temperature distribution in the rotary axis system must be considered in greater detail during the design process:
■ Asymmetrical rotary axis housings can undergo asymmetrical deformation due to heating.
■ In turn, out-of-round bearing seats lead to additional bearing load, reduced life and a negative influence on running behaviour and running accuracy.
■ Temperature management of the rotary axis in the form of targeted cooling and heating is generally necessary for high performance rotary axes. For simulation work, the Schaeffler Group has high performance simulation tools available.

Where there is non-uniform temperature distribution between the inner and outer ring, rotary axis bearings with ball contact (ZKLDF) show more tolerant behaviour than rotary axis bearings with line contact (such as axial/radial cylindrical roller bearings or crossed roller bearings).

The stated bearing characteristics only apply if the bearing preload remains unchanged. The bearing preload can be altered by mechanical stresses, such as those which can be caused by temperature differences or adjacent machine elements (such as force-locking clamping connections for example).
Axial/radial bearings
Axial angular contact ball bearings

Design regulations

Proven design regulations based on practical experiences, 

Figure 10:

- The contact face between the stator of the torque motor and 
  the rotary table housing should be as small as possible, in order 
  to minimise the flow of heat between stator and rotary table 
  housing.
- Where possible, do not connect the casing of the stator cooling 
  system to the rotary table housing.
- In preference, flange mount the rotor of the torque motor 
  on the rotary table plate rather than on the bearing, to keep 
  the flow of heat through the bearing to a minimum.
- The distance between the motor and the bearing should be 
  as large as possible. A large distance reduces the transfer 
  of heat from the rotor to the bearing. The stresses occurring 
  between the components as a result of varying thermal 
  expansion are reduced by the increased elasticity of the system.
- The rotary table plate bearing must be centered with sufficient 
  rigidity to allow the overall system to attain a high level of rigidity. 
  The risk of deformation to the bearing seat due to the increase 
  in the temperature of the rotor is also reduced.
- Use torque motors which are suitable for the requirements only, 
  with low loss of power and a high motor constant. We recommend 
  using IDAM torque motors.

Regulated cooling of the stationary and rotating components 
may be required in order to limit the temperature variations between 
the bearing inner and outer ring.

\[ Q = \text{heat flow} \]
\[ x = \text{distance from torque motor to bearing} \]

4. Rotor of the torque motor
5. Rotary table plate

Figure 10
Ideal rotary table, 
taking account of the occurring heat
Bearing preload
Once the bearings have been fitted and fully screw mounted, they are radially and axially clearance-free and preloaded.

Temperature differences
Temperature differences between the shaft and housing influence the radial bearing preload and thus the operating behaviour and operating life of the bearing arrangement.
If the shaft temperature is higher than the housing temperature, the radial preload will increase proportionally, so there will be an increase in the rolling element load, bearing friction and bearing temperature, while the operating life will be reduced.
If the shaft temperature is lower than the housing temperature, the radial preload will decrease proportionally, so the rigidity will decrease to bearing clearance. There will be an increase in wear, the operating life will be reduced and noise due to slippage may occur.

Frictional torque
The bearing frictional torque $M_F$ is influenced primarily by the viscosity and quantity of the lubricant and the bearing preload:
- The lubricant viscosity is dependent on the lubricant grade and operating temperature.
- When relubrication is carried out, the lubricant quantity is increased for a short time until the grease is distributed and the excess quantity has left the bearing.
- During initial operation and after relubrication, bearing friction is increased until the lubricant has been distributed within the bearing.
- The bearing preload is dependent on the mounting fits, the geometrical accuracy of the adjacent parts, the temperature difference between the inner and outer ring, the screw tightening torque and mounting situation (bearing inner ring axially supported on one or both sides).

In the case of series YRT, the bearing frictional torque is heavily influenced by the tightening torque of the inner ring fixing screws. As a result, the preload in the axial bearing parts can be increased by using screws of grade 12.9 and the corresponding tightening torque if required.
If a lower frictional torque is to be achieved, this can, for example, be realised by reducing the screw tightening torque. As the self-locking function of the screw connection which secures against loosening is also reduced as a result, the screws must be secured using suitable thread lockers.
For applications which are sensitive to frictional torque, we recommend using series ZKLDF or YRTS.
Axial/radial bearings
Axial angular contact ball bearings

Guide values for frictional torque $M_R$

The stated frictional torques $M_R$ are statistically determined guide values for bearings with grease lubrication after a grease distribution cycle and at an operating temperature of $\theta = 50^\circ C$, Figure 11 to Figure 13 and Figure 15, page 21. For mounting with an unsupported L-section ring for YRTC and YRTS, the measured frictional torque values, Figure 11 and Figure 12 apply. In the mounting variant with an L-section ring supported over its whole surface, these values are increased as a function of the washer thickness and the geometrical accuracy of the supporting ring by an average of 10% to 20%. The guide values for the frictional torque for axial/radial bearings YRT were determined at a measurement speed $n = 5 \text{ min}^{-1}$, see dimension table.

Deviations from the tightening torque of the fixing screws will have a detrimental effect on the preload and the frictional torque. For YRT bearings, it must be taken into consideration that the frictional torque can increase by a factor 2 to 2.5 with increasing speed.

$M_R = \text{frictional torque}$

$n = \text{speed}$

\[ n = \text{speed} \]

**Figure 13**
Frictional torques as guide values for ZKLDF, statistically determined values from series of measurements
Axial/radial bearings
Axial angular contact ball bearings

Relubrication and initial operation
The speed capability, friction, rating life, functional capability and the durations of relubrication intervals are essentially influenced by the grease used, see table.

Axial/radial bearings YRT, YRTC and YRTS can be relubricated via a lubrication groove in the L-section ring and the outer ring.

Axial angular contact ball bearings ZKLDF can be relubricated via a lubrication groove in the outer ring.

The bearing series YRTC, YRTS and ZKLDF have an additional lubrication connector in the screw mounting face of the outer ring. This allows reliable feed of lubricant even where there is a large fit clearance in the bearing seat or the outer ring is free, Figure 14.

For calculation of the relubrication quantities and intervals based on a stated load spectrum (speed, load, operating duration) and the environmental conditions, please contact us.

Options for relubrication

1. Relubrication via the lubrication groove in the outer ring
2. Relubrication via the outer ring screw mounting face
**Initial operation**

Rolling bearings may exhibit increased frictional torque during initial operation, which can lead to overheating where there is immediate operation at high speeds.

In order to prevent overheating of the bearing, the running-in cycle must always be carried out, *Figure 15*. The cycle may be shortened if there is appropriate monitoring of the bearing temperature.

The bearing ring temperature must not exceed +60 °C.

In the case of swivel type axes (low speed or small operating duration), the running-in cycle is not required.

**Overlubrication**

The bearings may be damaged by overheating as a result of increased frictional torque when operating at high speeds if they have been accidentally overlubricated.

In order to achieve the original frictional torque again, the running-in cycle in accordance with *Figure 15* should be carried out.

---

*Figure 15*

Running-in cycle for initial operation and after overlubrication

---

**Further information**

- The further information on lubrication in Catalogue HR 1, chapter Lubrication must be observed.

\[ n_G = \text{limiting speed according to dimension tables} \]

\[ t = \text{time} \]
**Axial/radial bearings**

**Axial angular contact ball bearings**

YRT, YRTS and ZKLDF have almost the same mounting dimensions.

Geometrical defects in the screw mounting surfaces and fits will influence the running accuracy, preload and running characteristics of the bearing arrangement. The accuracy of the adjacent surfaces must therefore be matched to the overall accuracy requirement of the subassembly. The tolerances of the adjacent surfaces must lie within the running tolerance of the bearing.

The adjacent construction should be produced in accordance with Figure 16 and the tolerances must be in accordance with the tables starting on page 25. Any deviations will influence the bearing frictional torque, running accuracy and running characteristics.

---

**Legend**

1) Tolerance class: see tables, page 25 to page 26. Support over whole bearing height. It must be ensured that the means of support has adequate rigidity.

2) Tolerance class: see tables, page 25 to page 26. A precise fit is only necessary if radial support due to the load or a precise bearing position is required.

3) Note the bearing diameter D1 in the dimension tables. Ensure that there is sufficient distance between the rotating bearing rings and the adjacent construction.

4) Values, see table Maximum corner radii of the fit surfaces, page 26.
Fits
The selection of fits leads to transition fits, i.e. depending on the actual dimensional position of the bearing diameter and mounting dimensions, clearance fits or interference fits can arise.

The fit influences, for example, the running accuracy of the bearing and its dynamic characteristics.

An excessively tight fit will increase the radial bearing preload. As a result:
- there is an increase in bearing friction and heat generation in the bearing as well as the load on the raceway system and wear
- there will be a decrease in the achievable speed and the bearing operating life.

For easier matching of the adjacent construction to the actual bearing dimensions, each bearing of series YRT and YRTS is supplied with a measurement record (this is available by agreement for other series).

Axial and radial runout accuracy of the bearing arrangement
The axial and radial runout accuracy is influenced by:
- the running accuracy of the bearing
- the geometrical accuracy of the adjacent surfaces
- the fit between the rotating bearing ring and adjacent component.

For very high running accuracy, the rotating bearing ring should ideally have a fit clearance 0 and it should be ensured that the bearing has preload in operation, see page 17.

Recommended fits for shafts
The shaft should be produced to tolerance class h5 and for series YRTS in accordance with table, page 26.

If there are special requirements, the fit clearance must be further restricted within the stated tolerance classes:
- Requirements for running accuracy:
  For maximum running accuracy and with a rotating bearing inner ring, the aim should be to achieve as close as possible to a fit clearance 0. The fit clearance may otherwise increase the bearing radial runout. With normal requirements for running accuracy or a stationary bearing inner ring, the shaft for series YRT, YRTC and ZKLDF should be produced to h5. For axial/radial bearing YRTS, the recommended fits for shaft and housing bore must be observed, see table, page 26.
- Requirements for dynamic characteristics:
  - For swivel type operation (n·d < 35 000 min⁻¹ · mm, operating duration ED < 10%) the shaft should be produced to h5. The tolerance class h5 can be used under these operating conditions for series YRT, YRTC, YRTS and ZKLDF.
  - For higher speeds and longer operating duration, the fit interference must not exceed 0,01 mm. For series YRTS, the fit interference must not exceed 0,005 mm.
  For series ZKLDF, the fit clearance should be based on the inner ring with the smallest bore dimension.
Axial/radial bearings
Axial angular contact ball bearings

Recommended fits for housings

The housing should be produced to tolerance class J6 and for series YRTS in accordance with table Recommended fits for shaft and housing bore for YRTS, page 26.

If there are special requirements, the fit clearance must be further restricted within the stated tolerance classes:

- Requirements for running accuracy:
  - For maximum running accuracy and with a rotating bearing outer ring, the aim should be to achieve as close as possible to a fit clearance of 0. With a static bearing outer ring, a clearance fit or a design without radial centring should be selected.

- Requirements for dynamic characteristics:
  - For predominantly swivel type operation ($n < 35,000 \text{ min}^{-1}$, $d < 100 \text{ mm}$) and a rotating bearing outer ring, the housing fit should be produced to tolerance class J6. The tolerance class J6 can be used under these operating conditions for series YRT, YRTC, YRTS and ZKLDF.
  - For axial/radial bearing YRTS with a higher speed and operating duration, a thermal FE calculation of the subassembly must be carried out.

If the calculations show a higher temperature at the shaft and bearing inner ring than at the bearing outer ring, it may be advantageous not to centre the bearing outer ring radially or to produce the housing fit as a clearance fit with at least 0.02 mm clearance. This will reduce the increase in preload that occurs where there is a temperature differential between the inner ring and outer ring of the bearing. However, if the temperature differential is too great, this may lead to overloading of the screw connections of the outer ring and the screw connection will start to slip. The result of this is radial clearance in the bearing arrangement of a cold machine.

If the calculations at the bearing outer ring show an identical or higher temperature in relation to the inner ring, then the housing should be produced in accordance with the recommended fits for shaft and housing bore for YRTS, see table, page 26.

Fit selection depending on the screw connection of the bearing rings

If the bearing outer ring is screw mounted on the static component, a fit seating is not required or a fit seating can be produced as stated, see tables, page 25 to page 26. If the values in the table are used, this will give a transition fit with a tendency towards clearance fit. This generally allows easy fitting.

If the bearing inner ring is screw mounted on the static component, it should nevertheless for functional reasons be supported by the shaft over the whole bearing height. The shaft dimensions should then be selected accordingly, see tables, page 25 to page 26. If these values in the table are used, this will give a transition fit with a tendency towards clearance fit.
Geometrical and positional accuracy of the adjacent construction

The values given in the following tables for geometrical and positional accuracy of the adjacent construction have proved effective in practice and are adequate for the majority of applications.

The geometrical tolerances influence the axial and radial runout accuracy of the subassembly as well as the bearing frictional torque and the running characteristics.

</table>
Mounting dimensions $H_1$, $H_2$

If the height variation must be as small as possible, the $H_1$ dimensional tolerance must conform to the tables, page 33 and page 34, and Figure 17.

The mounting dimension $H_2$ defines the position of any worm wheel used, Figure 17 and Figure 18, page 28, L-section ring with support ring.

![Figure 17](image)

Mounting dimension $H_1$, $H_2$

L-section ring without support ring or with support ring

The outward-facing axial surfaces of the shaft-mounted bearing rings of YRT (C, S) and ZKLDF can be mounted supported over their whole surface on one or both sides, Figure 18, page 28. The support ring (for example a worm wheel or torque motor) is not included in the scope of delivery.

In bearings of series ZKLDF, the rigidity and frictional torque are not influenced by the support ring.

In fitting of the series YRT (C, S) with an L-section ring supported axially over its whole surface, there is an increase in the axial rigidity in the direction of the support ring as a function of the support ring rigidity and in the tilting rigidity of the bearing position. In the case of YRT, the tilting rigidity can be increased by up to 20% in this way. In this case, delivery with a different preload match is necessary for YRT and YRTC, suffix VSP.

If the normal design of series YRT or YRTC (without suffix VSP) is mounted with a supported L-section ring, there will be a considerable increase in the bearing frictional torque.

The shaft locating washer must be supported axially over its whole surface by the adjacent construction. In the case of YRT..- VSP, the L-section ring must also be axially supported over its whole surface in order to achieve the stated rigidity values.

For series YRTS and ZKLDF, there is only one preload match. In YRTS bearings, the increase in rigidity and frictional torque is slight and can normally be ignored, see page 18.
Axial/radial bearings
Axial angular contact ball bearings

L-section ring without support ring
In the case of "L-section ring without support ring", the bearing designation is:
■ YRT <bore diameter>.

L-section ring with support ring
For the case "L-section ring with support ring", the bearing designation is:
■ YRT <bore diameter> VSP.

In the case of series YRT, the height of the support ring should be at least as large as the dimension H₂ of the bearing.

Any mounting conditions that deviate from our suggestions, Figure 18, may impair the function and the performance data of the bearings. For different designs, please contact us.

Design of fixing threads in the adjacent construction

Produce the thread in the adjacent construction with a cylindrical countersink to ensure bearing running accuracy, Figure 19 and table. If the cylindrical countersink is not applied, the surface may become deformed when the fixing screws are tightened.

Design of countersink

- $d_1 =$ countersink diameter
- $t =$ countersink depth

Improved ease of mounting

In order to ensure that the lubrication hole in the bearing is correctly positioned relative to the lubrication hole in the machine housing, the bearings YRTC, YRTS and ZKLDF have a so-called pilot pin hole, see table and Figure 20.

<table>

Fitting

Retaining screws secure the bearing components during transport. For easier centring of the bearing, the screws should be loosened before fitting and either secured again or removed after fitting. Tighten the fixing screws in a crosswise sequence using a torque wrench in three stages to the specified tightening torque $M_A$, while rotating the bearing ZKLDF, *Figure 21*:

- Stage 1 40% of $M_A$
- Stage 2 70% of $M_A$
- Stage 3 100% of $M_A$

Observe the correct grade of the fixing screws.

Mounting forces must only be applied to the bearing ring to be fitted, never through the rolling elements.

Bearing components must not be separated or interchanged during fitting and dismantling.

If the bearing is unusually difficult to move, loosen the fixing screws and tighten them again in steps in a crosswise sequence. This will eliminate any distortion.

Bearings should only be fitted in accordance with TPI 103, Fitting and Maintenance Manual.

*Figure 21*

Tightening of fixing screws
Axial/radial bearings
Axial angular contact ball bearings

Static rigidity

The overall rigidity of a bearing position is a description of the magnitude of the displacement of the rotational axis from its ideal position under load. The static rigidity thus has a direct influence on the accuracy of the machining results.

The dimension tables give the rigidity values for the complete bearing position, see page 36 to page 43. These take account of the deflection of the rolling element set as well as the deformation of the bearing rings and the screw connections.

The values for the rolling element sets are calculated rigidity values and are for information purposes only. They facilitate comparison with other bearing types, since rolling bearing catalogues generally only give the higher rigidity values for the rolling element set.

In the case of series YRT and YRTS, the axial rigidity in the corresponding direction and the tilting rigidity can be increased by supporting the L-section ring over its whole surface. The tilting rigidity is increased by up to 20% as a function of the thickness of the support washer.
**Accuracy**

The dimensional tolerances are derived from tolerance class 5. The diameter tolerances stated are mean values in accordance with ISO 1132.

The geometrical tolerances correspond to tolerance class 4 in accordance with ISO 492 (DIN 620-2), see table.

The bearing bore in series YRT, YRTC and YRTS may be slightly conical in the delivered condition. This is typical of the bearing design and is a result of the radial bearing preload forces. The bearing will regain its ideal geometry when fitted.

---

SRM

SRMC
Axial/radial bearings with angular measuring system

Features

Axial/radial bearings with angular measuring system comprise:
■ an axial/radial bearing YRTM or YRTSM with a dimensional scale, an SRM electronic measuring system and signal leads SRMC. The electronic measuring system SRM comprises two measuring heads, two stacks of shims and an electronic evaluation system. The signal leads for connecting the measuring heads to the electronic evaluation system can be ordered individually in various designs. The electronic measuring system MEKO/U will continue to be available but should no longer be used for new designs.

Bearings of series YRTM or YRTSM correspond in mechanical terms to axial/radial bearings YRT or YRTS but are additionally fitted with a magnetic dimensional scale. The measuring system can measure angles to an accuracy of a few angular seconds by non-contact, magneto-resistive means.

Advantages of the angular measuring system

The measuring system, Figure 1, page 48:
■ allows, due to the rigid connection to the adjacent construction, very good control characteristics (control stability and dynamics) and is therefore particularly suitable for axes with torque motor drive
■ offers a high maximum speed of up to 16,5 m/s
■ operates by non-contact means and is therefore not subject to wear
■ carries out measurement irrespective of tilting and position
■ has automatically self-adjusting electronics
■ has a self-centring function
■ is unaffected by lubricants
■ is easy to fit, the measuring heads are easily adjustable, there is no need for alignment of the bearing and a separate measuring system
■ requires no additional parts
  – the dimensional scale and measuring heads are integrated in the bearing and adjacent construction respectively
  – the resulting space saved can be used for the machining area of the machine
■ does not give any problems relating to supply cables. The cables can be laid within the adjacent construction directly through the large bearing bore
■ gives savings on design envelope size and costs due to the compact, integrated design requiring fewer components.
Axial/radial bearings with angular measuring system

The dimensional scale is applied without seams or joins to the outside diameter of the shaft locating washer. The magnetically hard coating has magnetic poles at a pitch of 250 μm that serve as angle references, Figure 2.

The angular position is measured incrementally, i.e. by counting the individual increments. For a fixed datum point for the angular position after the machine is switched on, an additional reference mark is therefore also required.

The system has pitch-coded reference marks in order to quickly create the absolute datum point. Every 15°, reference marks are applied with defined different pitches, so that the absolute datum point is achieved by passing over two adjacent reference marks (maximum 30°).
Measuring heads with magneto-resistive sensors

The measuring heads are colour coded:
- the silver measuring head (white) scans the incremental track
- the gold measuring head (yellow) scans the incremental track and the reference marks.

The two measuring heads are designed for optimum use of space. They are fixed in a slot in the adjacent construction by means of two fixing screws.

MR effect

The small magnetic fields are detected as a result of the magneto-resistive effect (MR effect). Compared with magnetic heads, the MR sensors allow static measurement of magnetic fields, i.e. electrical signals are derived without movement, in contrast to magnetic heads.

The resistance layer of the MR sensors is designed such that the resistance changes when a magnetic field is perpendicular to the current flow.

When the magnetic pitch moves past the MR sensor, two sine wave signals with a phase offset of 90° are generated with a period length of 500 μm.

O-rings for sealing

The measuring heads have O-rings to seal against the egress of oil and the ingress of fluids such as cooling lubricants.

Electronic evaluation system

The electronic evaluation system operates with the aid of a digital signal processor (DSP).

The input signals are digitised by an analogue/digital converter. The high performance processor (DSP) automatically compares the sensor signals and calculates the effective angular value from the sensor signals by means of vector addition. Correction is carried out, for example, on the offset of the analogue signals. A digital/analogue converter generates synthetic analogue signals as a 1 VSS value.

The electronic evaluation system can be positioned at any location or within the adjacent construction. It is connected to the controller by means of a conventional 12-pin extension cable.

The lead for transmitting the voltage signals from the electronic evaluation system to the electronic post-processor can be up to 100 m long.
Axial/radial bearings
with angular measuring system

Cables for signal transmission
The signal cables for connecting the measuring heads to the electronic evaluation system are available in the lengths 1 m, 2 m and 3 m, see table, page 51.
The connection side for the electronic evaluation system has a straight plug. The connection side to the measuring head is suitable for straight plugs or 90° elbow plugs.
In the case of the elbow plug, the cable outlet direction is defined in relation to the mounting position of the measuring heads.

Advantages
The cables are suitable for use in machinery and plant for chip-forming machining:
- the cables and plugs are shielded
- the cable sheathing is made from polyurethane (PUR), halogen-free and flame-resistant
- the signal cables are free from halogens, silicones and PVC as well as resistant to microbes and hydrolysis
- the cables are resistant to oils, greases and cooling lubricants
- the cables are suitable for dynamic use in flexible trunking (it must be ensured that they are laid correctly).

Bending cycles
When laid in flexible trunking, the cables can achieve \( \geq 2 \text{ million bending cycles} \) under the following test conditions:
- bending radius 65 mm (10\( \times \)D)
- acceleration 5 m/s\(^2\)
- travel speed 200 m/min
- travel distance 5 m, horizontally.

Plug connectors
INA plug connectors are robust and designed for use in industrial environments. When connected, they conform to protection grade IP 65 (DIN EN 60529).
The large sheathed areas of the plugs ensure effective shielding.
Connection cables

Measuring heads are connected using cables with 90° elbow plugs or cables with straight plugs, Figure 3.

Figure 3
Connection cable

Other designs available by agreement.

Dimensions of plugs and measuring heads, see page 77.

Use cables of the same length for connecting the two measuring heads in a measuring system.
Axial/radial bearings with angular measuring system

Setting and diagnosis program

The distance between the measuring heads and the outside diameter of the shaft locating washer is set using the setting and diagnosis software MEKOEDS, Figure 12, page 69 and see MON 18, Axial/radial bearings with angular measuring system. The software is also used to check the function of the fitted measuring system and detect defects in the measuring system. MEKOEDS is supplied on a USB memory stick, Figure 4. The USB memory stick also contains the appropriate manuals, see page 71. The current version of MEKOEDS and the manuals is available at www.schaeffler.com.

Interface cable

The measuring system is connected to a PC (serial interface) using the interface cable, Figure 4. The interface cable is included in the delivery of MEKOEDS, the length is 5 m. If the PC does not have a serial interface, we recommend the use of a conventional serial/USB converter, which is not included in the delivery.

The measuring system data can be recorded, displayed in diagram form, printed out and sent by e-mail to the Schaeffler Group for evaluation.
Measurement accuracy

The more accurate the angular measurement, the more accurately a rotary axis can be positioned. The accuracy of angular measurement is essentially determined by:

1. the quality of the dimensional scale
2. the quality of scanning
3. the quality of the electronic evaluation system
4. the eccentricity of the dimensional scale to the bearing raceway system
5. the runout deviation of the bearing arrangement
6. the elasticity of the measurement system shaft and its linkage to the shaft to be measured
7. the elasticity of the stator shaft and shaft coupling.

For the measuring system integrated in the bearing, only points 1 to 3 are relevant. The eccentricity in point 4 is completely eliminated by the diametrically opposed arrangement of the MR sensors. Points 5 to 7 play only a very minor role in the INA measuring system.

Positional deviations

Positional deviations within a revolution are the absolute measurement errors over one revolution of the system (measured at +20 °C ambient temperature):

- YRTM150 ≤ ±6”
- YRTM180 ≤ ±5”
- YRT(S)M200, YRT(S)M260, YRT(S)M325, YRT(S)M395, YRT(S)M460 ≤ ±3”.

Since the dimensional scale is directly connected, i.e. without any compensation elements, with the rolling bearing, deflections in the bearing raceway system due to machining forces could affect the measurement result. This effect is eliminated by the diametrically opposed arrangement of the measuring heads in the electronic evaluation system.
Axial/radial bearings
with angular measuring system

**Measurement record**

Each INA measuring system is supplied with an accuracy measurement record, *Figure 5.*

The accuracy is measured on the coded washer of the YRTM or YRTSM bearing when the coding is applied and is documented.

The measurement trace shows the pitch error of the coding.

[Figure 5]

Excerpt from a measurement trace, example:
YRTM 395 – serial no. 03/09/004

1. Measurement travel in degrees
2. Deviation in angular seconds
Error-free signal transmission

If the INA measuring system is fitted and operated as specified, it fulfils the requirements of Directives 89/336/EEC and 92/031/EEC for electromagnetic compatibility (EMC).

Adherence to the EMC directive in accordance with the following standards is demonstrated:

- EN 61000-6-2 Immunity
  - ESD:
    EN 61000-4-2
  - radiated electromagnetic fields:
    EN 61000-4-3
  - burst:
    EN 61000-4-4
  - surge:
    EN 61000-4-5
  - conducted immunity:
    EN 61000-4-6
  - magnetic field:
    EN 61000-4-8

- EN 55 011-B Emission
  - interference voltage:
    EN 55 011-B
  - perturbing radiation:
    EN 55 011-B.

Possible sources of electrical interference in the transmission of measurement signals

Disruptive voltage is mainly generated and transmitted by capacitive or inductive interference. Interference can occur through lines and equipment inputs and outputs.

Sources of interference include:

- strong magnetic fields due to transformers and electric motors
- relays, contactors and solenoid valves
- high frequency equipment, pulse devices and magnetic stray fields due to switched-mode power supply units
- supply mains and leads to the equipment mentioned above.

Interference in initial operation can generally be attributed to absent or inadequate shielding of the measurement leads or insufficient spacing between the signal and power cables.

The overall design should be such that the function of the measuring system is not influenced by sources of electrical or mechanical interference.
Axial/radial bearings
with angular measuring system

Measures to protect against interference

The precision bearing and measuring system must be handled with care.
The dimensional scale and sensor surface of the measuring heads are unprotected once the protective covers have been removed.
Screw the electronic evaluation system firmly to the earthed machine frame, Figure 6. If screw mounting surfaces are non-conductive, one of the fixing screws should be connected by electrically conductive means over the largest possible cross-section and a short route with the machine frame; all measuring system components must have the same potential.
The bearing components must be connected by electrically conductive means with equipotential bonding.
For signal connections, only shielded plug connectors and cables should be used.

Electronic evaluation system
Shielded plug connectors and cable
Adjacent construction
CNC (electronic post-processing system)

Figure 6
Shielding and post-processor
Protection against magnetic fields

Magnetic fields will damage or erase the dimensional scale. This will lead in some cases to mismeasurement by the system.

Magnetic sources must be kept away from the magnetic scale on the outside diameter of the shaft locating washer. A field strength of approx. 70 mT or higher immediately on the coding carries the risk of damage to the magnetic increments.

Magnetic dial gauge stands must not be placed directly on the coded washer; the guide value is at least 100 mm distance in air or 10 mm unalloyed steel, Figure 7 and Figure 8.

Never touch the coding with magnetisable objects. Typical examples are knives, screwdrivers and dial gauge feelers. Prevent contact with magnetisable contaminants. These could otherwise be deposited on the coding and lead to impaired measurement accuracy.

This could be due to:
- contamination of the lubricant, for example due to the oil bath
- contamination washed off by condensation, e.g. in conjunction with cooling devices
- wear debris from gears.

Figure 7
Minimum distance between magnetic dial gauge stand and shaft locating washer

Figure 8
Shielding by unalloyed steel
Axial/radial bearings
with angular measuring system

Pressing down
the measuring head by hand

In order to protect the sensor chip against damage, the measuring head can only be pressed against the dimensional scale by hand. Forces $> 50$ N can lead to sensor damage.

Laying of signal cables

Laying of disruptive and suppressed or non-disruptive cables in parallel and in spatial vicinity should be avoided. Separation in air of $> 100$ mm is recommended. If adequate spacing cannot be achieved, additional shielding or earthed metallic partition walls between the cables should be provided.

The requirement for spatial separation of cables also applies to typical sources of interference such as servo drives, frequency converters, contactors, solenoid valves and choking coils.

Crossings

If cables must be crossed, this should be carried out at a $90^\circ$ angle if possible.

Overlong cables

Overlong cables that are located rolled up in the switch cabinet will act as antennae and cause unnecessary interference. These cables should be cut to the required length.

Shielding

If shield separations are necessary, these should be reconnected over as large an area as possible. The free lead ends to the connector terminal should be as short as possible. Shield separations are a functional risk and should therefore be avoided.

Ends not required

Non-assigned ends should be connected on both sides with reference potential (chassis ground).

Motor connectors

No other cables for data cabling should be fed within shielded motor cables or terminal boxes for motor connectors. Spatial separation is also recommended here, for example by sheet metal partitions.

Interference suppression filter

Connections between interference suppression filters and the emission source should be kept as short as possible and should be shielded.
Compatibility
The analogue output signals 1 V_{CC} of the incremental track can be processed by all conventional CNC controllers.

For new applications, it should be checked whether the CNC controller can be parametrised in accordance with the technical data of the YRTM or YRTSM.

For most controllers, the input parameters can be requested from us.

Input of pulse rate
On many controllers, the pulse rate can be directly inputted. Pulse rate, see table, page 62. In isolated cases, however, this is carried out via a whole number multiplication and division value.

In these cases, the pulse rate cannot be entered exactly for sizes YRTM200 or YRTSM200 and YRTM395 or YRTSM395 and must be corrected using other parameters.

Pitch-coded reference marks
Some controllers cannot record signals from pitch-coded measuring systems. For these cases, the electronic measuring system can be supplied as a single reference mark measuring system. Please state this in the order text.

The differential pitch between two adjacent reference marks is two signal periods. In the zero transition area, the system design of the encoder leads to a large difference. The controller must be capable of processing this aspect.

In swivel type axes, the measuring system zero point (marked on the bearing using a drill bit) can be placed outside the scanning range of the yellow measuring head.

With continuous monitoring of the pitch-coded reference marks, the limiting speed \( n_G \) for the reference travel must not be exceeded, see dimension table.
Axial/radial bearings
with angular measuring system

Test according to standard
The functional capability has been tested under changing climatic conditions, under mechanical load and in contact with water, oil and cooling lubricants.

Climatic tests
The measuring system design has been tested in accordance with the following standards.

</tbody>
</table>
**Mechanical tests**

The measuring system design has been tested in accordance with the following standards.

- **DIN EN 60086-2-6**
- **MIL-STD-202, 204 C**

### Vibration, sine wave (measuring heads)

- According to standard: IEC 68-2-6
- Frequency range: 10 Hz to 2 kHz
- Vibration amplitude: ±0.76 mm (10 Hz to 60 Hz), 100 m/s² (60 Hz to 2 kHz)
- Rate: 1 octave/min
- Load duration: 240 min per axis
- Number of frequency cycles: 16 per axis
- Load directions: All three main axes

### Shocks (measuring heads)

- According to standard: IEC 68-2-27
- Acceleration: 30 g
- Shock duration: 18 m/s
- Shock type: Semisine wave
- Number of shock cycles: 6 per axis
- Load directions: All three main axes (i.e. a total of 18 cycles)

### IP protection type, protection against ingress of water

The measuring system design has been tested in accordance with the following standards.

- According to standard: DIN 40050-9
- Protection type: IP67

Ingress protection testing is carried out with water as a medium and over a limited time period. All push-fit connections are fitted. The measuring system should therefore be fitted with protection against cooling lubricants.

### Chemical resistance (measuring heads)

The measuring system design has been tested in accordance with the following standards.

- **Test media**
  - Mineral oil Aral Degol BG150
  - PAO Mobilgear SHC XMP150
  - Ester Shell Omala EPB150
  - PG Klüber Klübersynth GH6-150

- **Storage temperature**: +60 °C
- **Storage duration**: 168 hours

- **Test media**
  - Unitech Hosmac SL145
  - ZG Zubora 92F MR
  - Oemeta Hycut ET46
  - Unitech Hosmac S558

- **Storage temperature**: +35 °C
- **Storage duration**: 168 hours
- **Concentration**: 5% in water

For different operating conditions, please contact us.

Axial/radial bearings with angular measuring system

Detection of zero position, functional principle

The CNC checks whether the signals 1 to 3 are positive, see red quadrants, Figure 9. The zero position is then calculated, where $1 = \text{MAX (90°)}$, $2 = \text{ZERO (0°)}$.

The reference signal form has no influence. It is important to highlight more than this one quadrant, but not more than one signal period.

Special designs

The SRM electronic measuring system is also available as a single reference mark measuring system. Please state this in the order text.
Design and safety guidelines
Design of adjacent construction

The locating bore for the measuring head should have a chamfer $1 \times 30^\circ$; the lead chamfer for the O ring of the measuring head.

The measuring head should be centred in all planes on the shaft locating washer and secured against rotation by means of a locating surface.

For centring of the coded shaft locating washer, the bearing must be supported over its entire height by the adjacent construction of the shaft.

It is absolutely essential that the following are checked:

- The depth of the slot for the measuring heads conforms to dimension A, see table Recess diameter and distance and Figure 10, page 66.
- The screw mounting faces of the measuring heads are free from burrs and flat.
- The arrangement of the measuring heads is $180^\circ \pm 1^\circ$, Figure 10, page 66 and Figure 11, page 68.
- The recess diameter $D_{A\text{ min}}$ is machined in the adjacent construction for mounting of the bearing and the reliable function of the measuring system, see table.
- The distance $F$ is maintained after the measuring heads are fitted, see table and Figure 10, page 66.
- The cable exit direction corresponds to the illustration, Figure 10, page 66 when using cables with $90^\circ$ elbow plugs.
- Cables at the height of the measuring heads are relieved of tension. Especially where $90^\circ$ elbow plugs are used, cable tension forces can lead to overloading of the plugs.

Recess diameter and distance
Axial/radial bearings with angular measuring system

If the measuring heads are located deep in the housing, they must be sufficiently accessible to allow setting of the measurement gap.

The measuring heads and cable must be protected by a suitable cover against mechanical damage and long term contact with fluids.

The positional orientation of the measuring heads is determined by the locating face. It is not sufficient to determine the positioning exclusively by means of the fixing screws.

Observe the minimum bending radii for signal cables.

Fluids must not be allowed to build up in the measuring head pockets (IP67).
Safety-related information about the measuring device under the terms of the Machinery Directive

The angular measuring system meets the described product characteristics when used correctly. The measuring system is not suitable for use in safety-related control circuits and should not be used for this purpose. For systems with a safety focus, the positional value of the measuring device must be checked after the higher level system has been switched on. The measuring device is not developed in accordance with IEC 61508 and no SIL classification exists.

Characteristics of the measuring device relevant to hazard analysis:
■ The system does not have redundant functional elements.
■ Software is involved in generating the output signals.
■ If the following events occur, a zero voltage signal is outputted by the electronic evaluation system once the initial operation procedure is complete, that can be detected by a suitable electronic post-processing system as an error:
  – defect in the power supply
  – error in plausibility testing of the two measuring head signals by means of 4 quadrant operation (detection of measuring head failure or loose connections, for example cable breakage)
  – undershoot in the permissible minimum amplitudes of the measuring head signal (detection of measuring head failure, detection of an impermissibly large increase in the measurement gap, for example after a machine crash).
Axial/radial bearings with angular measuring system

Fitting
Due to the integrated dimensional scale and the small measuring heads designed for optimum use of available space, the measuring system is very easy to install.

Fitting guidelines for the axial/radial bearing
During fitting, the coded shaft locating washer is centred precisely by means of the shaft journal manufactured precisely over the whole bearing height.

Before fitting, the retaining screws on the inner ring should be loosened so that the bearing inner ring and shaft locating washer with the dimensional scale can align and centre themselves to each other without any force.

! Do not use magnetised tools.
The magnetic dimensional scale has a protective strip for transport and fitting.
Do not remove the protective strip until after the bearing is fitted.
Note the additional information on fitting of axial/radial bearings YRTM or YRTSM, see TPI 103, High precision bearings for combined loads.

Fitting guidelines for measuring heads
The mounting position of the measuring heads is specified by the design of the locating pockets.

Diametrically opposed arrangement of measuring heads
The arrangement of the measuring heads must not be smaller or greater than a diametrically opposed arrangement of 180° ± 1°, otherwise any eccentricities in the shaft locating washer will affect the measurement accuracy, Figure 10, page 66 and Figure 11.

Figure 11
Diametrically opposed arrangement of measuring heads
Fitting of measuring heads

First set the measuring heads using the MEKOEDS software and the shims supplied to the correct distance from the outside diameter of the shaft locating washer, Figure 12 and page 52. Setting: see MON 18, Axial/radial bearings with angular measuring system.

The software is then used to carry out a Teach-In process that matches the measuring heads to the electronic evaluation system.

Tighten the fixing screws carefully. Do not exceed an amplitude display of 80% in the MEKOEDS software during setting. The sensor surface of the measuring head must only be subjected to load by hand pressure. Forces > 50 N may damage the sensor surface.

The fixing screws for the measuring heads must be secured using Loctite (such that they can removed again), Figure 12.

Maximum screw tightening torque $M_A = 10$ Nm.

![Figure 12](image)

Fitting of measuring head

Cables and plugs for signal transmission

The plugs for the input signals to the electronic evaluation system are of an 8 pin type.

At first Teach-In, the system automatically detects which measuring head (white or yellow) is connected to which input.

The measuring heads, plugs and cables must be protected from mechanical damage.
Axial/radial bearings with angular measuring system

Ordering example, ordering designation

An axial/radial bearing of size 395 is required with measuring system, Figure 13.

The unit comprises:
- Axial/radial bearing: YRTSM395
- Electronic measuring system: SRM01
- Two connection cables with 90° elbow plugs on the measuring head side for connecting to the electronic evaluation system, each cable 2 m long: SRMC2-A

Ordering designation: YRTSM395/SRM01/(2 pieces) SRMC2-A

Two cables must be ordered for each measuring system unit.

Figure 13
Ordering example, ordering designation:
- Unit

1. YRTSM395
2. Measuring heads
3. Shims
4. Electronic evaluation system
5. Connection cables
Also required...
The following are also required:
- Setting and diagnosis software (MEKOEDS)
  (USB memory stick with interface cable, 5 m, can be used as often as required)
- Fitting and maintenance manual for the bearing (TPI 103)
- Teach-In and diagnosis manual for the measuring system (MON 18)
Both manuals are held on the USB memory stick as PDF files.

Ordering designation
MEKOEDS
The manuals TPI 103, High precision bearings for combined loads, and MON 18, Axial/radial bearings with angular measuring system, can also be obtained in printed form from Schaeffler.

Replacement parts
The following replacement parts are available, Figure 13, page 70:
- Only shaft locating washer with coding WSM YRT
  >bearing bore diameter<
- Measuring head with reference sensor (yellow) SRMH ye
- Measuring head without reference sensor (white) SRMH wh
- Shims (packet) SS-SRM
- Electronic evaluation system SRMB
Axial/radial bearings
Double direction
With measuring system

YRTM

1) Including retaining screws or threaded extraction holes.
2) Measurement speed $n_{const} = 5 \text{ min}^{-1}$, bearing temperature $+50 \, ^\circ\text{C}$, after grease distribution cycle; frictional torque can only increase by 2,5 times up to the limiting speed.
3) Rigidity values taking account of the rolling element set, deformation of the bearing rings and the screw connections.
4) Attention!
   For fixing holes in the adjacent construction.
   Note the pitch of the bearing holes.
5) Tightening torque for screws to DIN 912, grade 10.9.
6) The measuring head cannot be mounted between the fixing holes or the heads of the fixing screws. Two holes for fixing screws therefore remain unused in the bearing outer ring.
7) Attention!
   H and $H_1$ are 1 mm higher than standard bearings YRT.
8) Screw counterbores in the L-section ring open to the bearing bore.
The bearing inside diameter is unsupported in the area (2).

</table>

Screw counterbore open \[^{(3)}\]
Bearing inside diameter unsupported in area \( \textcircled{2} \)

---

1. Two retaining screws

---

[Image: Hole pattern]
The feeler cables are connected internally to the supply cable (2 with 12 and 11 with 10). They are used by the motor controller as a measurement cable in order to compensate the voltage drop on the supply cable (four-wire principle). If this function is not supported by the controller used, the two 5-V cables and both 0-V cables can be wired in parallel in order to reduce the voltage drop on the supply lead.

The housing is shielded.

**Electronic evaluation system** (protection class IP67):
1. Connection for RS232
2. 2 holes for fixing screws DIN 912-M4×10
3. Shielded plug with cable to electronic post-processing system (not included in delivery).
Measuring head ①, connection cable SRMC..-A ② and SRMC..-S ③.
(Design of connection cable see page 51)
